ARTICLE INFO	ABSTRACT
Article history: Received 20211127	Sugar beet is commercially grown in Minnesota, Idaho, North Dakota, Michigan, Nebraska, Montana, California, Wyoming, Colorado, Oregon, and Washington [3].The
Received in revised form 20211207 Accepted 20211217 Available online 20211227	cultivars are relatively high-yielding and are moderately resistant to most of the common soil-borne and foliar pathogens. Most cultivars have a minimum level of resistance to root pathogens such as <i>Rhizoctoniasolani</i> , <i>Aphanomyces cochlioides</i> , <i>Clonostachysrosea</i> , — <i>Globisporangiumultimum</i> , <i>Rhizopus stolonifera</i> , and <i>Fusarium equiseti</i> [1, 2, 3, 4].
Keywords: Barley;	. Otootsporangtumutimum, Knizopus stotonyera, and Pusartum equisett [1, 2, 3, 4].

In June 2019, sugar beet seedlings were observed with hypocotyl and root rot in Sidney (47.7167° N, 104.1563° W), Montana. The disease affected about 20% of the 10 ha commercial field (Fig. 1). Hypocotyl of infected seedlings was surface sterilized with 70% ethanol for 30 seconds, rinsed with sterile distilled water, and cultured on 10% water agar (WA) for 7 days at 25°C. Macroscopically, on WA the colonies had profusewhite cottony mycelia with black dot-like heads (Fig. 2). Microscopically, the sporangiophores developed in groups (3 to 5) simple rhizoids and stolons at their ends (Fig. 3). The globose sporangia were large with a size of 90.24 (50.67 to 140.55) µm, and the sporangiospores ranged from ellipsoid to ovoid and measured 5.55 (5.00–8.14) μ m × 3.4 (2.92–5.46) μ m. Based on the morphological characteristics, the fungus was identified as Rhizopus stolonifer[5].Pathogenicity assay was done using 8, 2-week old sugar beet seedlings grown individually in pots (4"×4"×6"). Seedlings were inoculated with a mycelial plug which was kept close to the seedlings. Inoculated and control plants were placed in the greenhouse at $25 \pm 2^{\circ}$ C,

and 80% to 85% relative humidity. In 4-5 days, six out of 8 inoculated seedlings showed symptoms similar to those observed in the field and non-inoculated seedlings were symptomless. This study was repeated (Fig. 4). The fungus was isolated from diseased roots and confirmed to be *Rhizopus stolonifer* based on morphological characters. *Rhizopus stolonifer* and *R. arrhizus* are the most common fungi mostly found in moist agricultural soils. *Rhizopus stolonifer* causes disease at low temperatures of 57° to 61°F. Recently, *Globisporangiumultimum* was reported to cause constriction on hypocotyl of sugar beet seedlings[4]. To our knowledge, this is the first report of *Rhizopus stolonifer* causing hypocotyl and root rot on sugar beet seedlings in Montana.
